Classification

Part 1

Prof. Bisbee

Vanderbilt University

Slides Updated: 2024-03-19

Agenda

- 1. Classification
- 2. Fortnite gaming (i.e., Prof's desperate attempt to be relevant)

```
read_rds('https://github.com/jbisbee1/DS1000_S2024/raw/main/data/fn_cle
require(tidyverse)
```

Definitions

• Classification: predicting the class of given data points via predictive modeling

o Class: AKA targets, labels, or categories

 \circ *Predictive Modeling*: Approximate mapping function f:X o Y

 $\circ \ X$: predictor variables

 $\circ \ Y$: outcome variable

∘ f: 5?

Classification

Mapping Functions

We have already used a mapping functions!

Linear Regression

$$\circ \ f{:}\, Y = \alpha + \beta X + \varepsilon$$

ullet Underlying idea: X contain information about Y

It is in the Y

ullet If Y is continuous, we use OLS regression

- If Y is \emph{binary} , we use "logistic" regression (AKA "logit")

As always, this is a deep area of study for those interested

 $\bullet\,$ Today, using OLS for binary Y

Next few classes: replacing OLS regression with logit

Fortnite

Fortnite

Goal is to win (i.e., be the last player alive)

Professional e-sports teams want to maximize this probability

RQ: How can we increase the number of victories?

• NB: we are moving out of the Research camp now, and into the **Prediction** world • We don't care so much about why a relationship exists, we just want to get accurate predictions

 Theory can still help us, but want to start with the data to get our thinking started

The Data

                                     $ placed
                                                                                                                                                                                                                                                                                                                                                           gameId
```

Classification

Start with the basics:

The Data

1. What is the unit of analysis?

2. Which variables are we interested in?

Prediction

$$Y = \alpha + \beta_1 X_1 + \beta_2 X_2 + \dots + \varepsilon$$

• Y: victory (won)

• X: 55

In prediction, we don't care about theory or research questions

 \circ Just want to maximize **accuracy**...which X's are the "best"?

 $\circ\,$ But theory can still help us make sensible choices about which X s to

Look at univariate & conditional relationships

The Data

ullet Outcome Y: won

```
= percent(mean(won)))
                           summarise(`Win %`
require(scales)
fn %>%
```

```
## # A tibble: 1 × 1
## `Win %`
## <chr>
## 1 30%
```

Multivariate analysis?

3/19/24, 4:17 PM

```
group_by(mental_state) %>%
summarise(pr_win = mean(won))
fn %>%
```

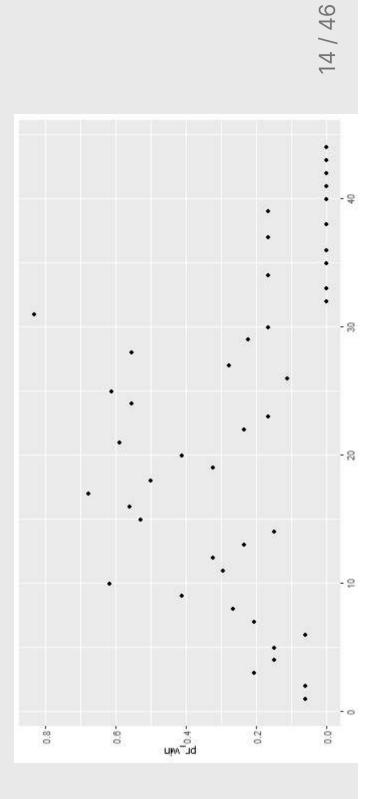

```
0.234
         mental_state pr_win
<chr><</pre>
## # A tibble: 2 \times 2
                     ## <chr> ## 1 high ## 2 sober
```

Which X?

```
fn %>%
  group_by(gameIdSession) %>%
  summarise(pr_win = mean(won))
```

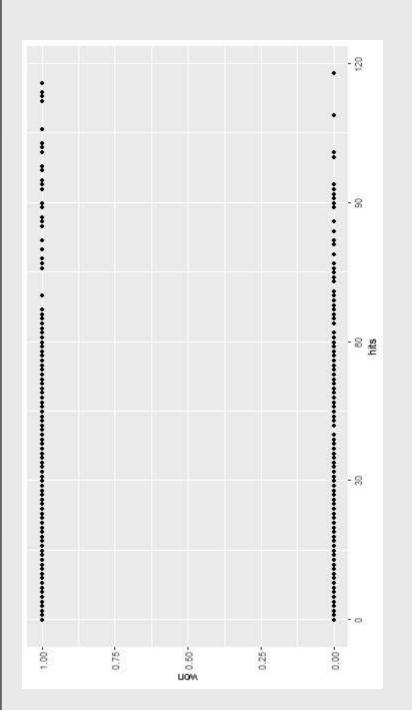

```
1 0.0588
2 0.0588
3 0.206
4 0.147
5 0.147
6 0.0588
7 0.206
8 0.265
9 0.412
         gameIdSession pr_win
<int> <dbl>
# A tibble: 44 × 2
                                                                                                                                  34 more rows
```

Which X?

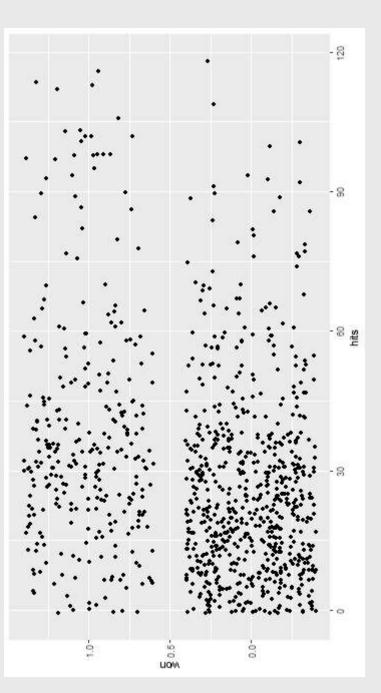

Which X?

```
fn %>%
ggplot(aes(x = hits,y = won)) +
geom_point()
```

Which X?

ggplot(aes(x = hits,y = won)) +
geom_jitter() fn %>%

Heatmaps

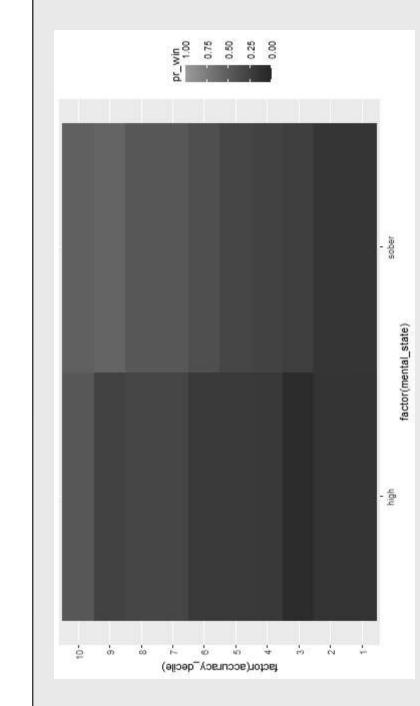

- Look at 3-dimensions of data
- Done this before by tweaking fill, color, or size
- geom_tile(): create a heatmap

```
mutate(accuracy_decile = ntile(hits,n=10)) %>% # Bin hits by decile
                                                                                                                                                                                                                                                                                                                fill = pr_win)) + # Fill by third dimension
geom_tile() + # Creates rectangles
scale_fill_gradient(limits = c(0,1)) # Set fill color (can do much
                                                                                                                                                                                                                                                     y = factor(accuracy\_decile), # Both x and y-axes are
                                                                                        group_by(accuracy_decile,mental_state) %>% # Calculate average
                                                                                                                                                          winning by mental state and accuracy
p <- fn %>%

Heatmaps

Simplest Predictions

Remember: regression is just fancier conditional means

```
group_by(hits_decile,mental_state) %>% # Calculate average winning
mutate(hits_decile = ntile(hits,n=10)) %>% # Bin hits by decile
                                                                                                                                                                           mutate(prob_win = mean(won)) %>% # use mutate() instead of
summarise() to avoid collapsing the data
                                                                                                                                                                                                                                                                                mutate(pred_win = ifelse(prob_win > .5,1,0)) %>% # If the
probability is greater than 50-50, predict a win
                                                                                                                                                 by mental state and accuracy
```

Simplest Predictions

Conditional means

```
П
                       summarise(nGames=n(),.groups
group_by(won,pred_win) %>%
```

```
<int>
                won pred_win nGames
# A tibble: 4 × 3
```

- How good is this? Think about the underlying goal...we want a model that accurately predicts whether a game is won or not
- The won column is the truth...it tells us whether the game was won or not
- The pred_win column is our prediction

Classification

Accuracy

- What is "accuracy"?
- Proportion "correct" predictions
- For a binary outcome, "accuracy" has two dimensions
- Proportion of correct 1s: Sensitivity
- Proportion of correct 0s: Specificity

Accuracy

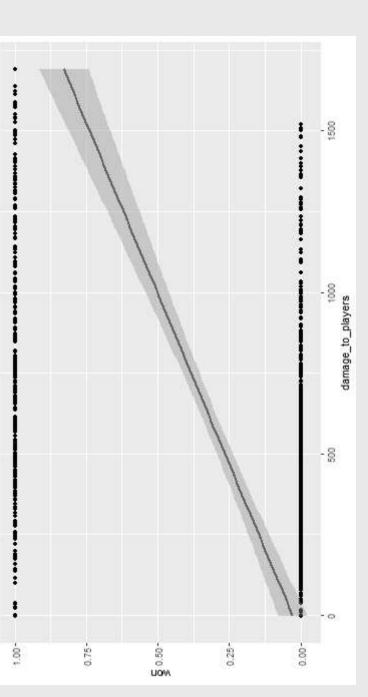

```
group_by(won) %>%
mutate(total_games = n()) %>%
group_by(won,pred_win,total_games) %>%
summarise(nGames=n(),.groups = 'drop') %>%
mutate(prop = nGames / total_games))
(sumTab <- fn %>%
```

```
41 0.0616
241 0.828
            prop
<dbl>
                                625 0.938
                     <int> <int>
         won pred_win total_games nGames
                                999
                                          999
                                                    291
291
## # A tibble: 4 \times 5
                    ##
```

- Overall accuracy: (625+50) / (666+291) = 71%
- But we are doing great at predicting losses (94%)...
- ...and terribly at predicting wins (17%)

Regression

```
ggplot(aes(x = damage_to_players,y = won)) +
geom_point() +
geom_smooth(method = 'lm')
fn %>%
```

3/19/24, 4:17 PM

Classification

Regression

- Binary outcome variable!
- A linear regression is not the best solution
- $\circ\,$ Predictions can exceed support of Y
- But it can still work! linear probability model

Linear Regression

```
require(broom) # broom package makes it easy to read regression
                                                 output
```

```
tidy(mLM) %>% # This would be the same as summary(mLM)
                                                                                                                                               mutate_at(vars(-term),function(x) round(x,5))

# A tibble: 4 × 6
```

Classification

Evaluating Predictions

Overall accuracy is just the number of correct predictions (either 0 or 1) out of all possible

o Is 71% good?

What would the dumbest guess be? Never win! 70%

Might also want to care about just 1s

Sensitivity: Predicted wins / actual wins = 22%

Also might care about just 0s

Specificity: Predicted losses / actual losses = 92%

Thresholds

Shifting the threshold for 0 or 1 prediction can matter

```
mutate(accuracy = percent(sum((won == pred_win)*nGames) /
mutate(pred_win = ifelse(predict(mLM) > .4,1,0)) %>%
group_by(won) %>%
                                                                                                             group_by(won,pred_win,total_games) %>%

toplot <- NULL
```

Thresholds

We might only care about accuracy by itself (although this is a bit naive)

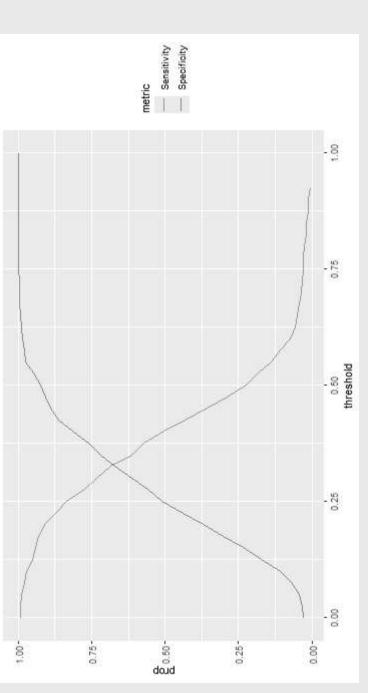

```
ggplot(aes(x = threshold,y = accuracy)) +
geom_line()
                 select(accuracy,threshold) %>%
distinct() %>%
toplot %>%
```

Classification

Thresholds

```
drop_na(metric) %>%
ggplot(aes(x = threshold,y = prop,color = metric)) +
geom_line()
toplot %>%
```

ROC Curve

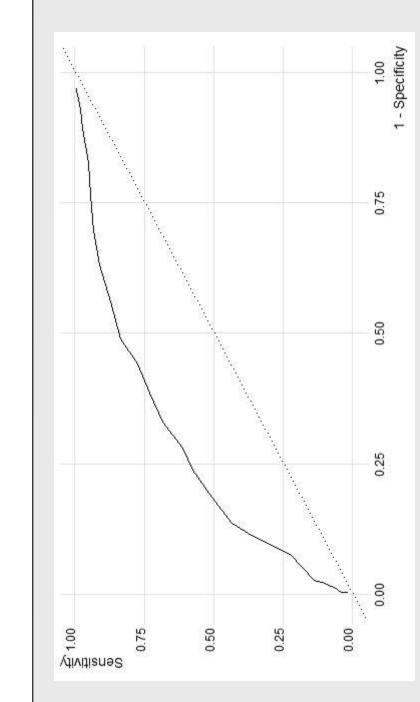

- Receiver-Operator Characteristic (ROC) Curve
- Commonly used to evaluate classification methods
- X-axis: 1-specificity
- Y-axis: sensitivity

```
mutate(metric = ifelse(won == 1 & pred_win == 1, 'Sensitivity',

AUC

What is a "good" AUC?

perfectly wrong) and 1 (i.e., it predicts everything perfectly correct) We know it is bounded between 0 (i.e., it predicts everything

But typically we don't see AUC values less than 0.5 (why is this?)

AUC can be interpreted like numeric grades at Vandy (and for this class)

o 0.95+ is amazing

0.9 - 0.95 is very good

0.8-range is B-tier

o 0.7-range is C-tier

o 0.6-range is really bad

AUC values less than 0.6 are failing

Classification

Party time!

Adding more variables / trying different combinations

• Workflow

1. Train models

2. Predict models

3. Evaluate models

Train models

```

```

Cross Validation AUC

```
ggplot(aes(x = .estimate,y = factor(reorder(model,.estimate)))) +
    geom_boxplot() + labs(x = 'Distribution of AUC',y =
'Specification')
cvRes %>%
```

Classification

Conclusion

- Classification is just a type of prediction
- We used linear regression
- But there are much fancier algorithms out there
- Next class:
- A slightly fancier algorithm: logistic regression
- How to use the models to achieve the team's goals
- Go to Brightspace and take the 14th quiz
